Householder Triangularization: Numerics

3 of 3

The Moral of the Story

The errors in Q_2 and R_2 are known as forward errors. Large forward errors are the result of an ill-conditioned problem and/or an unstable algorithm. — In our example it is the former

 $\kappa(A) = \text{cond}(A) = 2.0223\text{e+}16.$

np.linalg.cond

The error in the result of the matrix product Q_2R_2 is known as the backward error. or residual.

The fact that the backward error is small suggests that Householder Triangularization is backward stable.

Note: Due to the specific way the Householder reflections are performed, the algorithm above may have to be run a couple of times in order to produce (similar) results. A relative error in Q_2 of size ~ 2 indicates that the initial random Q and R Ê could not possibly have come from a HT-QR algorithm (due to "sign-flips.") SAN DIEGO ST

Now, we define \tilde{Q} to be the exactly unitary matrix

$$\tilde{Q} = \tilde{Q}_1 \tilde{Q}_2 \cdots \tilde{Q}_n,$$

this matrix will take the place of the computed Q in our discussion.

This approach is natural since in general the matrix Q is not formed explicitly, but rather used implicitly to get the action $Q^*\vec{b}$.

With these definitions, we are ready to state the theorem...

Householder Triangularization: Backward Stability

It turns out that HT-QR is backward stable for **all** matrices A in any floating-point environment satisfying the floating point axioms.

The formal result takes the form

$$ilde{Q} ilde{R}=A+\delta A,\qquad \delta A$$
 "small,"

where \tilde{R} is the upper triangular matrix constructed by the HT-QR algorithm.

Since the HT-QR algorithm does not explicitly compute \tilde{Q} (in the "fast mode,") we must define what we mean by \tilde{Q} .

Let \tilde{Q}_k denote the exactly unitary reflector defined by the floating point vector $\tilde{\mathbf{v}}_k$

$$ilde{Q}_k = I - 2 rac{ ilde{\mathbf{v}}_k ilde{\mathbf{v}}_k^*}{ ilde{\mathbf{v}}_k^* ilde{\mathbf{v}}_k}.$$

Theorem (Backward Stability of Householder QR)

Let the QR-factorization A = QR of a matrix $A \in \mathbb{C}^{m \times n}$ be computed by Householder triangularization in a floating-point environment satisfying the floating-point axioms, and let the computed factors \tilde{Q} and \tilde{R} be as discussed on the previous two slides. Then we have

$$ilde{Q} ilde{R} = A + \delta A, \quad rac{\|\delta A\|}{\|A\|} = \mathcal{O}(arepsilon_{\mathit{mach}})$$

for some $\delta A \in \mathbb{C}^{m \times n}$.

Computing the QR-factorization is not an end in itself. Usually it is one of the first steps in trying to solve a system of linear equations, a least squares problem, or an eigenvalue problem.	It turns out that this algorithm is backward stable. The three steps are backward stable. For now we state these results without proof, and then combine them to form the larger result.
At this point we know that HT–QR is backward stable, but is that enough?!? As we have seen, the individual factors \tilde{Q} and \tilde{R} may carry	We have already expressed the backward stability of ${\tt HT-QR}$ in a previous theorem.
large forward errors. The good news is that accuracy of the product $\tilde{Q}\tilde{R}$ is sufficient for most	The second step computes $\tilde{Q}^* \vec{b}$, due to floating-point errors, the result \tilde{y} is not equal to $\vec{y} = \tilde{Q}^* \vec{b}$, but the operation is backward stable
purposes. We consider the following algorithm for solving $A\vec{x} = \vec{b}$	$(ilde{Q}+\delta Q) ilde{y}=ec{b}, \ \delta Q\ =\mathcal{O}(arepsilon_{mach}).$

Patching Some Holes...

We have left three major holes in the argument — the statement, without* proof, that the individual steps are backward stable.

It is instructive to see at least one such proof from "scratch." — Next, we turn our attention to step-3, *the back-substitution algorithm*.

Even though back substitution is one of the easiest problems of numerical linear algebra, the stability proof is quite lengthy... and provides the general structure / workflow for all such proofs. \rightsquigarrow That will be our next order of business in [Lecture#13].

* For step-1 (the *QR*-factorization), we have "proof by reference."
