Recap Gram-Schmidt Gram-Schmidt and Householder: Different Views of QR

Projectors: Orthogonal and Non-Orthogonal

Classical Gram-Schmidt

Last Time (Projections: Classical Gram-Schmidt)

Orthogonal and non-orthogonal projectors

$$P=P^2, \qquad \left[P=P^*\right].$$

Projection with an orthonormal, and arbitrary, basis

$$P = \widehat{Q}\widehat{Q}^*, \qquad P = A(A^*A)^{-1}A^*.$$

Rank-one projections, rank-(m-1) complementary projections

$$P = \vec{q}\vec{q}^*, \qquad P_{\perp} = I - \vec{q}\vec{q}^*.$$

QR-Factorization, using classical Gram-Schmidt orthogonalization.

— (4/38)

Peter Blomgren (blomgren@sdsu.edu)

7. QR & LSQ: Gram-Schmidt and Householder

Algorithm: Classical Gram-Schmidt

∃ Movies

Algorithm (Classical Gram-Schmidt)

1: **for**
$$k \in \{1, ..., n\}$$
 do
2: $\vec{v}_k \leftarrow \vec{a}_k$
3: **for** $i \in \{1, ..., k-1\}$ **do**
4: $r_{ik} \leftarrow \vec{q}_i^* \vec{a}_k$
5: $\vec{v}_k \leftarrow \vec{v}_k - r_{ik} \vec{q}_i$

5:
$$v_k \leftarrow v_k - r_{ik}$$
6: **end for**
7: $r_{kk} \leftarrow \|\vec{v}_k\|_2$
8: $\vec{a}_k \leftarrow \vec{v}_k/r_{kk}$

Mathematically, we are done. Numerically, however, we can run into trouble due to roundoff errors.

Gram-Schmidt Gram-Schmidt and Householder: Different Views of QR

Bad News for the Classical Version Improving Gram-Schmidt I Feel the Need for Speed!!!

A Hard Test Problem

Matlab-centric Notation

Let U and V be two randomly selected (80 \times 80) unitary matrices

$$[U, \sim] = qr(randn(80,80)); [V, \sim] = qr(randn(80,80));$$

Build a matrix A with singular values $2^{-1}, 2^{-2}, \dots, 2^{-80}$: (condition number — $\kappa(A) = 2^{79} \approx 10^{23}$)

$$S = diag(2.^{(-1:-1:-80)}); A = U * S * V';$$

Finally we compute the QR-factorization using both classical and modified Gram-Schmidt

$$[QC,RC] = qr_cgs(A);^{HW#3} [QM,RM] = qr_mgs(A);^{HW#4}$$

Now, the diagonals of RC and RM contain the recovered singular values.

Burning Questions: What is the modified Gram-Schmidt method?!? ... and why do we need it?!?

(7/38)

Gram-Schmidt

Classical Gram-Schmidt: Revisited -- The Modified Gram-Schmidt Method

Let $A \in \mathbb{C}^{m \times n}$, $m \ge n$, be a full-rank matrix with columns \vec{a}_k . With orthogonal projectors P_k we can express the Gram-Schmidt orthogonalization using the formulas

$$\vec{q}_k = \frac{P_k \vec{a}_k}{\|P_k \vec{a}_k\|_2}, \quad k = 1, \dots, n$$

The projector P_k must be an $(m \times m)$ -matrix of rank (m-(k-1)) which projects the space \mathbb{C}^m orthogonally onto the space orthogonal to span $(\vec{q}_1, \ldots, \vec{q}_{k-1})$. $(P_1 = I)$.

Note: $\vec{q}_k \in \text{span}(\vec{a}_1, \dots, \vec{a}_k)$ and $\vec{q}_k \perp \text{span}(\vec{q}_1, \dots, \vec{q}_{k-1})$; therefore this description is equivalent to the algorithm on slide 5.

We can represent the projector $P_k = (I - \widehat{Q}_{k-1} \widehat{Q}_{k-1}^*)$ where \widehat{Q}_{k-1} is the $(m \times (k-1))$ -matrix $[\vec{q}_1 \ \vec{q}_2 \ \dots \ \vec{q}_{k-1}]$.

Bad News for the Classical Version Improving Gram-Schmidt I Feel the Need for Speed!!!

Classical Gram-Schmidt: The Bad News

1 of 2

Unfortunately, classical Gram-Schmidt is not numerically stable in finite precision, the vectors \vec{q}_k may lose orthogonality...

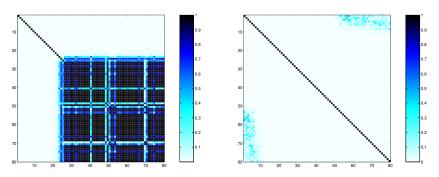

Figure: Comparing Q^*Q (which should be the identity matrix) for classical (left) and modified (right) Gram-Schmidt on a particularly hard problem where $\sigma_1 = 2^{-1}$ and $\sigma_{80} = 2^{-80}$. We see that CGS completely loses orthogonality after 20-some steps; whereas MGS does not suffer this catastrophic breakdown.

Bad News for the Classical Version Improving Gram-Schmidt

Improving Gram-Schmidt
I Feel the Need for Speed!!!

Classical Gram-Schmidt: The Bad News

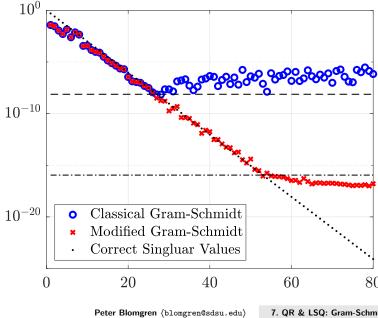

Figure: The performance of classical 'o's) (blue and modified (red 'x's) Gram-Schmidt on a particularly hard problem where $\sigma_1 = \frac{1}{2}$ and $\sigma_{80} = \frac{1}{2^{80}}$. C-GS identifies the first ~ 26 singular values (down to the size $\sim \sqrt{\varepsilon_{\rm mach}}$), whereas M-CG identifies ~ 54 singular values (down to the size $\sim \varepsilon_{\rm mach}$).

7. QR & LSQ: Gram-Schmidt and Householder

— (9/38)

Recap **Gram-Schmidt** Gram-Schmidt and Householder: Different Views of QR Bad News for the Classical Version Improving Gram-Schmidt I Feel the Need for Speed!!!

An Improvement: Modified Gram-Schmidt

For each k in classical Gram-Schmidt, we compute one orthogonal projection of rank (m - (k - 1)):

$$\vec{v}_k = P_k \vec{a}_k$$
.

Modified Gram-Schmidt computes the same — **mathematically equivalent** quantity — by a sequence of (k-1) projections of rank (m-1):

$$P_1 = I$$
, $P_k = P_{\perp \vec{a}_{k-1}} \dots P_{\perp \vec{a}_1}, \quad k > 1$,

where

$$P_{\perp \vec{q}_k} = I - \vec{q}_k \vec{q}_k^*, \quad k > 1,$$

thus

$$\mathbf{\tilde{v}_k} = \mathbf{P}_{\perp \tilde{\mathbf{q}}_{k-1}} \, \dots \, \mathbf{P}_{\perp \tilde{\mathbf{q}}_1} \mathbf{\tilde{a}}_k.$$

Gram-Schmidt and Householder: Different Views of QR

Bad News for the Classical Version Improving Gram-Schmidt

I Feel the Need for Speed!!!

What is "Machine Epsilon," $\varepsilon_{\text{mach}}$???

Machine Epsilon is the smallest positive value for which $1.0 + \varepsilon > 1.0$.

In most (double-precision / 64-bit) computational environments $\varepsilon_{\rm mach} \sim 2.22 \times 10^{-16}$, which means we can compute with AT MOST 15 significant (base-10) digits.

Recap

Gram-Schmidt

Algorithm (Find Machine Epsilon)

1:
$$eps = 1.0$$

2: **while**
$$(1.0 + eps > 1.0)$$
 do

$$eps \leftarrow eps/2$$

4: end while

5: $eps \leftarrow eps * 2$

Peter Blomgren (blomgren@sdsu.edu)

7. QR & LSQ: Gram-Schmidt and Householder

Bad News for the Classical Version Improving Gram-Schmidt

I Feel the Need for Speed!!!

Gram-Schmidt and Householder: Different Views of QR

Algorithm: Modified Gram-Schmidt

Algorithm (Modified Gram-Schmidt)

1: **for**
$$k \in \{1, ..., n\}$$
 do

2:
$$\vec{v}_k \leftarrow \vec{a}_k$$

3: end for

4: **for**
$$i \in \{1, ..., n\}$$
 do

5:
$$r_{ii} \leftarrow ||\vec{v}_i||_2$$

$$\vec{q}_i \leftarrow \vec{v}_i/r_{ii}$$

7: **for**
$$k \in \{(i+1), \ldots, n\}$$
 do

8:
$$r_{ik} \leftarrow \vec{q}_i^* \vec{v}_k$$

9:
$$\vec{v}_k \leftarrow \vec{v}_k - r_{ik} \vec{q}_i$$

The ordering of the computation is the key... in step #i, we make all the remaining columns orthogonal to column #i.

In practice, usually we let $\vec{v_i}$ overwrite $\vec{a_i}$, in order to save storage.

We can also let \vec{q}_i overwrite \vec{v}_i to save additional storage.

Recap **Gram-Schmidt** Gram-Schmidt and Householder: Different Views of QR Bad News for the Classical Version Improving Gram-Schmidt I Feel the Need for Speed!!!

Counting Work: Ancient, Old, and Somewhat Recent Measures

How fast is fast???

— (15/38)

Gram-Schmidt
Gram-Schmidt and Householder: Different Views of QR

Bad News for the Classical Version Improving Gram-Schmidt I Feel the Need for Speed!!!

Why is $\vec{q}_i^* \vec{v}_k \neq \vec{q}_i^* \vec{a}_k$???

In **infinite precision**, they are the same:

 \vec{v}_k contains only the part of $\vec{a}_k \perp \operatorname{span}(\vec{q}_1,\ldots,\vec{q}_{k-1})$, *i.e*

$$\vec{a}_k = \vec{v}_k + \vec{a}_k^{\dagger}, \quad \text{where } \vec{a}_k^{\dagger} \in \operatorname{span}\left(\vec{q}_1, \dots, \vec{q}_{k-1}\right)$$

in the sense that:

$$ec{q}_i^*ec{a}_k = ec{q}_i^*(ec{v}_k + ec{a}_k^\dagger) = ec{q}_i^*ec{v}_k + ec{q}_i^*ec{a}_k^\dagger = ec{q}_i^*ec{v}_k$$

However, *numerically*, throwing out the (infinite-precision) 0 is better than "mixing in" the numerical errors from the computation of $\vec{q}_i^* \vec{a}_k^{\dagger}$.

7. QR & LSQ: Gram-Schmidt and Householder

(14/20

Gram-Schmidt
Gram-Schmidt and Householder: Different Views of QR

Bad News for the Classical Version Improving Gram-Schmidt I Feel the Need for Speed!!!

Counting Work: Ancient, Old, and Somewhat Recent Measures

We need some measure of how fast, or slow, an algorithm is...

In **ancient times** multiplications (an divisions) where a lot slower than additions (and subtractions) $T_{*,/} \gg T_{+,-}$; so one would count the number of multiplications.

Then the chip designers figured out how to make multiplications faster, so $T_{*,/} \approx T_{+,-}$, so in the **old days** one would count all operations.

Last week, processors where so fast that **memory accesses** dominated the processing time; in particular **cache-misses**, so we end up with a completely different model... (see next slide)

Yesterday, processors suddenly had multiple cores, and hence multiple memory pathways...

This morning we have to deal with GPUs with tens of thousands of cores, FPGAs...

Bad News for the Classical Version Improving Gram-Schmidt

I Feel the Need for Speed!!!

Counting Work: The (Single-Threaded) Memory Access Latency Model

If we have three cache-levels (L1, L2, and L3), some average hit-rate (and hence miss-rate) for each level and the time it takes to access that cache-level (the hit-cycle-time), then we end up with a measure for the average memory access latency per memory access

$$T \sim (L1_hit_rate * L1_hit_cycle_time) + (L1_miss_L2_hit_rate * L2_hit_cycle_time) + (L2_miss_L3_hit_rate * L3_hit_cycle_time) + (L3_miss_rate * [S] DRAM_latency)$$

If this does not scare you, please get a Ph.D. in algorithm design! Meanwhile, the rest of us will count "flops", i.e. floating-point operations (multiplications and additions)!

Peter Blomgren (blomgren@sdsu.edu)

7. QR & LSQ: Gram-Schmidt and Householder

Recan Gram-Schmidt Gram-Schmidt and Householder: Different Views of QR

Bad News for the Classical Version Improving Gram-Schmidt I Feel the Need for Speed!!!

Counting Work: Gram-Schmidt Orthogonalization

Theorem (Computational Complexity of Modified Gram-Schmidt) The modified Gram-Schmidt orthogonalization algorithm requires

$$\sim 2mn^2$$
 flops

to compute the QR-factorization of an $(m \times n)$ matrix.

Here we have assumed that complex arithmetic is just as fast as real arithmetic. This is not true in general.

$$c_1 \cdot c_2 = [r_1 \cdot r_2 - i_1 \cdot i_2] + i [r_1 \cdot i_2 + r_2 \cdot i_1]$$

$$c_1 + c_2 = [r_1 + r_2] + i [i_1 + i_2]$$

Hence, the complex multiplication consists of 4 real multiplications and 2 real additions; and the complex addition consists of 2 real additions. Also, we need at least double the amount of memory accesses.

Bad News for the Classical Version

Gram-Schmidt Gram-Schmidt and Householder: Different Views of QR

Improving Gram-Schmidt I Feel the Need for Speed!!!

Counting Flops

The Outer Loop: for $i \in \{1, ..., n\}$

The Inner Loop: for $k \in \{(i+1), \ldots, n\}$

 r_{ik} is formed by an m-inner product -- requiring mmultiplications and (m-1) additions

 \vec{V}_k requires m multiplications and m subtractions

End Inner Loop

End Outer Loop

Work
$$\sim \sum_{i=1}^{n} \sum_{k=i+1}^{n} 4m \sim \sum_{i=1}^{n} 4m(n-i)$$

 $\sim 4mn^2 - 4mn^2/2 \sim 2mn^2$

Note that to *leading order* summation is "just like" integration:

$$\sum_{i=0}^n i^p \sim \frac{n^{(p+1)}}{(p+1)}$$

I Feel the Need for Speed!!!

Gram-Schmidt and Householder: Different Views of QR

Exact Summation Formula

For Reference

$$\sum_{k=0}^{n} i^{p} = \frac{(n+1)^{p+1}}{p+1} + \sum_{k=1}^{p} \frac{B_{k}}{p-k+1} \binom{p}{k} (n+1)^{p-k+1},$$

where B_k are Bernoulli numbers:

$$B_k(n) = \sum_{\ell=0}^k \sum_{\nu=0}^\ell (-1)^{\nu} {\ell \choose \nu} \frac{(n+\nu)^k}{\ell+1}.$$

Gram-Schmidt Gram-Schmidt and Householder: Different Views of QR

Gram-Schmidt — Triangular Orthogonalization Householder — Orthogonal Triangularization Householder vs. Gram-Schmidt

Gram-Schmidt as Triangular Orthogonalization

3 of 3

This formulation of the QR-factorization shows that we can **think** of the modified Gram-Schmidt algorithm as a method of triangular orthogonalization.

We apply a sequence of triangular operations from the right of the matrix A in order to reduce it to a matrix \widehat{Q} with orthonormal columns.

In practice we **do not** explicitly form the matrices R_i and multiply them together.

However, this view tells us something about the structure of modified Gram-Schmidt.

Note: From now on when we say "Gram-Schmidt" we mean the modified version.

Gram-Schmidt Gram-Schmidt and Householder: Different Views of QR Gram-Schmidt — Triangular Orthogonalization

Householder — Orthogonal Triangularization Householder vs. Gram-Schmidt

Final Comment: Gram-Schmidt Orthogonalization

Comment (Advantages and Disadvantages)

"The Gram-Schmidt process is inherently numerically unstable. While the application of the projections has an appealing geometric analogy to orthogonalization, the orthogonalization itself is prone to numerical error. A significant advantage however is the ease of implementation, which makes this a useful algorithm to use for prototyping if a pre-built linear algebra library is unavailable."

7. QR & LSQ: Gram-Schmidt and Householder

Gram-Schmidt Gram-Schmidt and Householder: Different Views of QR

Gram-Schmidt — Triangular Orthogonalization Householder — Orthogonal Triangularization

Householder vs. Gram-Schmidt

Householder Reflections

The matrices Q_k are of the form

$$Q_k = \left[\begin{array}{cc} I & 0 \\ 0 & F \end{array} \right],$$

where I is the $((k-1)\times(k-1))$ identity, and F is an $((m-k+1)\times(m-k+1))$ unitary matrix.

The matrix F is responsible for introducing zeros into the kth column.

Let $\vec{x} \in \mathbb{C}^{m-k+1}$ be the last (m-k+1) entries in the kth column.

$$\vec{x} = \begin{bmatrix} \times \\ \times \\ \vdots \\ \times \end{bmatrix} \quad \stackrel{F}{\rightarrow} \quad F\vec{x} = \begin{bmatrix} \pm \|\vec{x}\|_2 \\ 0 \\ \vdots \\ 0 \end{bmatrix} = \pm \|\vec{x}\|_2 \vec{e}_1.$$

Gram-Schmidt — Triangular Orthogonalization
Householder — Orthogonal Triangularization
Householder vs. Gram-Schmidt

Householder Reflections: A Geometric View

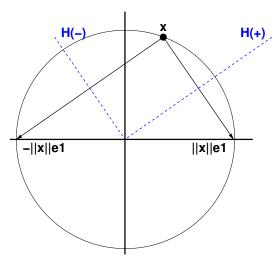

Figure: We can view the two points $\pm \|\vec{x}\|_2 \vec{e_1}$ as reflections across the hyperplanes, H_{\pm} , orthogonal to $\vec{v}_{\pm} = \pm \|\vec{x}\|_2 \vec{e_1} - \vec{x}$.

Peter Blomgren (blomgren@sdsu.edu)

7. QR & LSQ: Gram-Schmidt and Householder

— (29/38)

Recap Gram-Schmidt Gram-Schmidt — Triangular Orthogonalization
Householder — Orthogonal Triangularization
Householder vs. Gram-Schmidt

7. QR & LSQ: Gram-Schmidt and Householder

Householder Reflections: Which One?!?

Gram-Schmidt and Householder: Different Views of QR

In the real case we have two possibilities, i.e.

$$\vec{v}_{\pm} = \pm \|\vec{x}\|_2 \vec{e}_1 - \vec{x}, \quad \Rightarrow \quad F_{\pm} = I - 2 \frac{\vec{v}_{\pm} \vec{v}_{\pm}^*}{\vec{v}_{\pm}^* \vec{v}_{\pm}}.$$

Mathematically, both choices give us an algorithm which produces a triangularization of A. However, from a numerical point of view, the choice which **moves** \vec{x} **the farthest** is optimal.

If \vec{x} and $\|\vec{x}\|_2 \vec{e_1}$ are too close, then the vector $\vec{v} = (\|\vec{x}\|_2 \vec{e_1} - \vec{x})$ used in the reflection operation is the difference between two quantities that are almost the same — catastrophic **cancellation** may occur.

Therefore, we select

$$\tilde{\mathbf{v}} = -\text{sign}(\mathbf{x}_1) \|\tilde{\mathbf{x}}\|\tilde{\mathbf{e}}_1 - \tilde{\mathbf{x}} \stackrel{*}{\equiv} \text{sign}(\mathbf{x}_1) \|\tilde{\mathbf{x}}\|\tilde{\mathbf{e}}_1 + \tilde{\mathbf{x}}.$$

(*) We can take out the minus sign since \vec{v} always appears "squared" in the reflector.

Recap Gram-Schmidt Gram-Schmidt — Triangular Orthogonalization

Householder — Orthogonal Triangularization

Householder vs. Gram-Schmidt

Gram-Schmidt and Householder: Different Views of QR

Householder Reflections: As Projectors

We now use our knowledge of projectors and note that for any $\vec{y} \in \mathbb{C}^m$, the vector $P\vec{y}$ defined by

$$P\vec{y} = \left[I - \frac{\vec{v}\vec{v}^*}{\vec{v}^*\vec{v}}\right]\vec{y} = \vec{y} - \vec{v}\left[\frac{\vec{v}^*\vec{y}}{\vec{v}^*\vec{v}}\right],$$

is the orthogonal projection of \vec{y} onto the space H.

However, in order to **reflect across** the space H we must move the point twice as far, *i.e.*

$$F\vec{y} = \left[I - 2\frac{\vec{v}\vec{v}^*}{\vec{v}^*\vec{v}}\right]\vec{y} = \vec{y} - 2\vec{v}\left[\frac{\vec{v}^*\vec{y}}{\vec{v}^*\vec{v}}\right].$$

- 6: end for
- A(k:m,k) Denotes the kth thru mth rows, in the kth column of A a vector quantity.
- A(k:m,k:n) Denotes the kth thru mth rows, in the kth thru nth columns of A a matrix quantity.

Gram-Schmidt Gram-Schmidt and Householder: Different Views of QR

Gram-Schmidt — Triangular Orthogonalization Householder — Orthogonal Triangularization Householder vs. Gram-Schmidt

Householder-QR: Where is the Q?!?

1 of 2

At the completion of the Householder QR-factorization, the modified matrix A contains R (of the full QR-factorization), but Q is nowhere to be found.

Often, we only need Q implicitly, as in the **action** of Q on something. *I.e.* if we need $Q^*\vec{b}$, we can add the line

$$\vec{b}(\mathtt{k}:\mathtt{m}) \leftarrow \vec{b}(\mathtt{k}:\mathtt{m}) - 2\vec{v}_k(\vec{v}_k^*\vec{b}(\mathtt{k}:\mathtt{m}))$$

to the loop; or store the generated vectors \vec{v}_k , and a posteriori compute

Recap

for
$$k \in \{1, ..., n\}$$
 do
$$\vec{b}(\mathbf{k}:\mathbf{m}) \leftarrow \vec{b}(\mathbf{k}:\mathbf{m}) - 2\vec{v}_k(\vec{v}_k^* \vec{b}(\mathbf{k}:\mathbf{m}))$$
end for

Householder-QR: Where is the Q?!?

2 of 2

If we need $Q\vec{x}$, then we must store the generated vectors \vec{v}_k , and compute

for
$$k \in \{n, ..., 1\}$$
 do $\vec{x}(\mathtt{k}:\mathtt{m}) \leftarrow \vec{x}(\mathtt{k}:\mathtt{m}) - 2\vec{v}_k(\vec{v}_k^*\vec{x}(\mathtt{k}:\mathtt{m}))$ end for

We can also use this algorithm to explicitly generate Q

$$Q \leftarrow I_{n \times n}$$

for $k \in \{n, ..., 1\}$ do
 $Q(\texttt{k:m,k:n}) \leftarrow Q(\texttt{k:m,k:n}) - 2\vec{v}_k(\vec{v}_k^*Q(\texttt{k:m,k:n}))$
end for

2....

Householder-QR: Work

mgs: $\sim 2mn^2$

The dominating work is done in the operation

$$A(\mathtt{k}:\mathtt{m},\mathtt{k}:\mathtt{n}) \leftarrow A(\mathtt{k}:\mathtt{m},\mathtt{k}:\mathtt{n}) - 2\vec{v}_k(\vec{v}_k^*A(\mathtt{k}:\mathtt{m},\mathtt{k}:\mathtt{n}))$$

Each entry in A(k:m,k:n) is "touched" by 4 flops per iteration (2 from the inner product, 1 scalar multiplication, and 1 subtraction).

The size of the sub-matrix A(k:m,k:n) is $((m-k+1)\times(n-k+1))$, so we get

$$\sum_{k=1}^{n} (m-k+1)(n-k+1) \sim \sum_{k=1}^{n} (m-k)(n-k) \sim \sum_{k=1}^{n} (mn+k^2-k(m+n))$$

$$\sim mn^2 + \frac{n^3}{3} - \frac{n^2}{2}(m+n) \sim \frac{mn^2}{2} - \frac{n^3}{6}$$

Hence, the work of Householder-QR is $\sim 2mn^2 - \frac{2n^3}{3}$ flops.

Final Comment: Householder Reflections

Gram-Schmidt and Householder: Different Views of QR

Comment (Advantages and Disadvantages)

"The use of Householder transformations is inherently the most simple of the numerically stable QR decomposition algorithms due to the use of reflections as the mechanism for producing zeroes in the R matrix. However, the Householder reflection algorithm is bandwidth heavy and not parallelizable, as every reflection that produces a new zero element changes the entirety of both Q and R matrices."
