12. Stability of Householder QR for $A\vec{x} = \vec{b}$

Accuracy

Reference: Accuracy — The Goal!

Definition (Accuracy)

We say that the algorithm \tilde{f} is **accurate** if $\forall \vec{x} \in X$

Stability of Algorithms

Solving $A\vec{x} = \vec{b}$

$$rac{\| ilde{f}(ec{x}) - f(ec{x})\|}{\|f(ec{x})\|} = \mathcal{O}(arepsilon_{\mathsf{mach}}).$$

This is what we want to do — write algorithms that accurately solve problems!

Last time, we finally tied the inherent difficulty of the problem, the conditioning, and the quality of the algorithm, the stability together in a theorem —

— (7/26)

Definition (Backward Stable Algorithm)

An algorithm \tilde{f} is **backward stable** if $\forall \vec{x} \in X$

Reference

Solving $A\vec{x} = \vec{b}$

Stability of Algorithms

$$\tilde{f}(\vec{x}) = f(\tilde{\vec{x}}),$$

for some $\tilde{\vec{x}}$ with

$$rac{\| ilde{ec{x}}-ec{x}\|}{\|ec{x}\|}=\mathcal{O}(arepsilon_{\mathsf{mach}}).$$

"A backward stable algorithm gives exactly the right answer, to approximately the right question."

Jump to: accuracy theorem.

12. Stability of Householder QR for $A\vec{x} = \vec{b}$

Reference Stability of Algorithms Solving $A\vec{x} = \vec{b}$

Floating Point Axioms Stability Definitions Accuracy

Last Time: Accuracy(stability,conditioning)

Theorem (Computational Accuracy)

Suppose a backward stable algorithm is applied to solve a problem $f: X \to Y$ with condition number κ in a floating point environment satisfying the floating point representation axiom, and the fundamental axiom of floating point arithmetic.

Then the relative errors satisfy

$$\frac{\|\tilde{f}(x) - f(x)\|}{\|f(x)\|} = \mathcal{O}(\kappa(x)\varepsilon_{mach}).$$

Recall: The definition of the relative condition number

$$\kappa(\vec{x}) = \sup_{\delta \vec{x}} \left[\frac{\|\delta f\|}{\|f(\vec{x})\|} \middle/ \frac{\|\delta \vec{x}\|}{\|\vec{x}\|} \right]$$

as the ratio of the relative (infinitesimal) change in f induced by an infinitesimal change in \vec{x} .

The Road Ahead: Stability of Algorithms

With our new toolbox in hand, we re-visit some of the algorithms previously discussed. This second look will reveal, in a more rigorous way, why the algorithms perform the way they do...

The Householder Triangularization method of computing the QR-factorization is a backward stable (HT-QR for short).

First, we look at some numerical experiments showcasing this; and then we combine HT-QR with other backward stable algorithmic fragments to build a stable solver for our fundamental problem

$$A\vec{x} = \vec{b}$$
.

```
norm(Q2-Q) / norm(Q)
norm(R2-R) / norm(R)
                    = 0.000440
```

It seems like a disaster has occurred, but

```
norm(A-Q2*R2) / norm(A) = 1.032309e-15
```

It turns out that Q_2 and R_2 are quite far from Q and R:

Now consider Q_3 and R_3

```
QЗ
                               0 + 1e-4*randn(64)
                              R + 1e-4*randn(64)
norm(Q3-Q) / norm(Q)
                              0.001595
norm(R3-R) / norm(R)
                              0.000129
norm(A-Q3*R3) / norm(A)
                              1.065451e-03
```

Householder Triangularization: Numerics

3 of 3

The Moral of the Story

The errors in Q_2 and R_2 are known as **forward errors**. Large forward errors are the result of an ill-conditioned problem and/or an unstable algorithm. — In our example it is the former

$$\kappa(A) = \text{cond}(A) = 2.0223e+16.$$

np.linalg.cond

The error in the result of the matrix product Q_2R_2 is known as the **backward error**, or **residual**.

The fact that the backward error is small **suggests** that Householder Triangularization is backward stable.

Note: Due to the specific way the Householder reflections are performed, the algorithm above may have to be run a couple of times in order to produce (similar) results. A relative error in Q_2 of size ~ 2 indicates that the initial random Q and R could not possibly have come from a HT-QR algorithm (due to "sign-flips.")

Now, we define \tilde{Q} to be the exactly unitary matrix

$$\tilde{Q} = \tilde{Q}_1 \tilde{Q}_2 \cdots \tilde{Q}_n$$

this matrix will take the place of the computed Q in our discussion.

This approach is natural since in general the matrix Q is not formed explicitly, but rather used implicitly to get the **action** $Q^*\vec{b}$.

With these definitions, we are ready to state the theorem...

— (15/26)

Solving $A\vec{x} = \vec{b}$

Householder Triangularization: Backward Stability

1 of 3

It turns out that $\mathtt{HT-QR}$ is backward stable for **all** matrices A in any floating-point environment satisfying the floating point axioms.

The formal result takes the form

$$\tilde{Q}\tilde{R} = A + \delta A, \qquad \delta A \text{ "small,"}$$

where \tilde{R} is the upper triangular matrix constructed by the HT-QR algorithm.

Since the HT-QR algorithm does not explicitly compute \tilde{Q} (in the "fast mode,") we must define what we mean by \tilde{Q} .

Let \tilde{Q}_k denote the **exactly unitary** reflector defined by the floating point vector $\tilde{\mathbf{v}}_k$

$$ilde{Q}_k = I - 2 rac{ ilde{\mathbf{v}}_k ilde{\mathbf{v}}_k^*}{ ilde{\mathbf{v}}_k^* ilde{\mathbf{v}}_k}$$

Theorem (Backward Stability of Householder QR)

Let the QR-factorization A=QR of a matrix $A\in\mathbb{C}^{m\times n}$ be computed by Householder triangularization in a floating-point environment satisfying the floating-point axioms, and let the computed factors \tilde{Q} and \tilde{R} be as discussed on the previous two slides. Then we have

$$ilde{Q} ilde{R} = A + \delta A, \quad rac{\|\delta A\|}{\|A\|} = \mathcal{O}(arepsilon_{ ext{mach}})$$

for some $\delta A \in \mathbb{C}^{m \times n}$.

The full proof can be found in: —

Theorem — Householder-Triangularization + Back-Substitution Three Major Holes to Patch...

Solving $A\vec{x} = \vec{b}$, Using Householder QR-Factorization

1 of 8

Computing the QR-factorization is not an end in itself. Usually it is one of the first steps in trying to solve a system of linear equations, a least squares problem, or an eigenvalue problem.

At this point we know that HT-QR is backward stable, but is that enough?!? As we have seen, the individual factors \tilde{Q} and \tilde{R} may carry large forward errors.

The **good news** is that accuracy of the product $\tilde{Q}\tilde{R}$ is sufficient for most purposes.

We consider the following algorithm for solving $A\vec{x} = \vec{b}$

Algorithm (Solution of a Linear System, $A\vec{x} = \vec{b}$)

- Compute the QR-factorization by HT-QR
- Construct $Q^*\vec{b}$ by HT-QR
- $\vec{x} \leftarrow R^{-1} \vec{v}$ Solve by back substitution

Theorem — Householder-Triangularization + Back-Substitution Three Major Holes to Patch...

Solving $A\vec{x} = \vec{b}$, Using Householder QR-Factorization

3 of 8

With these unproven (for now) building blocks, we are ready to state and prove the following theorem

Theorem

The three step algorithm described above for solving $A\vec{x} = \vec{b}$ is backward stable, satisfying

$$(A+\Delta A) ilde{x}=ec{b},\quad rac{\|\Delta A\|}{\|A\|}=\mathcal{O}(arepsilon_{ extit{mach}}),$$

for some $\Delta A \in \mathbb{C}^{m \times m}$

— (19/26)

Stability of Algorithms Solving $A\vec{x} = \vec{b}$

Theorem — Householder-Triangularization + Back-Substitution Three Major Holes to Patch...

Solving $A\vec{x} = \vec{b}$, Using Householder QR-Factorization

2 of 8

It turns out that this algorithm is backward stable. The three steps are backward stable. For now we state these results without proof, and then combine them to form the larger result.

We have already expressed the backward stability of HT-QR in a previous theorem.

The second step computes $\tilde{Q}^*\vec{b}$, due to floating-point errors, the result \tilde{y} is not equal to $\vec{v} = \hat{Q}^* \vec{b}$, but the operation is backward stable

$$(\tilde{Q} + \delta Q)\tilde{y} = \vec{b}, \quad \|\delta Q\| = \mathcal{O}(arepsilon_{\mathsf{mach}}).$$

The solution \tilde{x} of the back substitution in the third step satisfies

$$(ilde{R}+\delta R) ilde{x}= ilde{y},\quad rac{\|\delta R\|}{\| ilde{R}\|}=\mathcal{O}(arepsilon_{\sf mach}).$$

Peter Blomgren (blomgren@sdsu.edu)

12. Stability of Householder QR for $A\vec{x} = \vec{b}$

-(18/26)

Stability of Algorithms Solving $A\vec{x} = \vec{b}$

Theorem — Householder-Triangularization + Back-Substitution Three Major Holes to Patch...

Solving $A\vec{x} = \vec{b}$, Using Householder *QR*-Factorization

4 of 8

Proof: From step #2 and step #3 we have

$$(\tilde{Q} + \delta Q)\tilde{y} = \vec{b}$$
, and $(\tilde{R} + \delta R)\tilde{x} = \tilde{y}$,

combining the two gives

$$ec{b} = (ilde{Q} + \delta Q)(ilde{R} + \delta R) ilde{x} = \left[ilde{Q} ilde{R} + (\delta Q) ilde{R} + ilde{Q}(\delta R) + (\delta Q)(\delta R)\right] ilde{x}.$$

Now, using the result for step #1

$$\tilde{Q}\tilde{R} = A + \delta A$$

we get

$$ec{b} = \left[A + \underbrace{\delta A + (\delta Q) ilde{R} + ilde{Q} (\delta R) + (\delta Q) (\delta R)}_{\Delta A}
ight] ilde{x}.$$

Theorem — Householder-Triangularization + Back-Substitution Three Major Holes to Patch...

Solving $A\vec{x} = \vec{b}$, Using Householder QR-Factorization

5 of 8

Next, we must show that the perturbation

$$\Delta A = \delta A + (\delta \mathbf{Q})\tilde{\mathbf{R}} + \tilde{Q}(\delta R) + (\delta Q)(\delta R)$$

is small relative to A.

Since $\tilde{Q}\tilde{R} = A + \delta A$, and \tilde{Q} is unitary we have $\tilde{R} = \tilde{Q}^*(A + \delta A)$

$$rac{\| ilde{R}\|}{\|A\|} \leq \| ilde{Q}^*\|rac{\|A+\delta A\|}{\|A\|} = \mathcal{O}(1), \quad arepsilon_{\sf mach} o 0.$$

Hence, the relative size of the second term is bounded

$$rac{\|(\delta Q) ilde{R}\|}{\|A\|} \leq \|(\delta Q)\|rac{\| ilde{R}\|}{\|A\|} = \mathcal{O}(arepsilon_{\mathsf{mach}}).$$

Peter Blomgren (blomgren@sdsu.edu)

12. Stability of Householder QR for $A\vec{x} = \vec{b}$

-(21/26)

Stability of Algorithms Solving $A\vec{x} = \vec{b}$ Theorem — Householder-Triangularization + Back-Substitution Three Major Holes to Patch...

Solving $A\vec{x} = \vec{b}$, Using Householder QR-Factorization

7 of 8

Finally, the fourth term

$$\Delta A = \delta A + (\delta Q)\tilde{R} + \tilde{Q}(\delta R) + (\delta \mathbf{Q})(\delta \mathbf{R})$$

$$\frac{\|(\delta Q)(\delta R)\|}{\|A\|} \leq \|(\delta Q)\| \frac{\|(\delta R)\|}{\|A\|}$$

We know

$$\|(\delta Q)\| = \mathcal{O}(arepsilon_{\mathsf{mach}}), \quad \mathsf{and} \quad rac{\|(\delta R)\|}{\|A\|} = \mathcal{O}(arepsilon_{\mathsf{mach}})$$

So.

$$rac{\|(\delta Q)(\delta R)\|}{\|A\|} = \mathcal{O}(arepsilon_{\mathsf{mach}}^2)$$

Stability of Algorithms Solving $A\vec{x} = \vec{b}$

Theorem — Householder-Triangularization + Back-Substitution Three Major Holes to Patch...

Solving $A\vec{x} = \vec{b}$, Using Householder QR-Factorization

6 of 8

Now, consider the third term

$$\Delta A = \delta A + (\delta Q)\tilde{R} + \tilde{\mathbf{Q}}(\delta \mathbf{R}) + (\delta Q)(\delta R)$$

$$\frac{\|\tilde{Q}(\delta R)\|}{\|A\|} \leq \|\tilde{Q}\| \frac{\|(\delta R)\|}{\|A\|} = \|\tilde{Q}\| \frac{\|(\delta R)\|}{\|\tilde{R}\|} \frac{\|\tilde{R}\|}{\|A\|}.$$

Since

$$\| ilde{Q}\| = \mathcal{O}(1), \quad rac{\|(\delta R)\|}{\| ilde{R}\|} = \mathcal{O}(arepsilon_{\mathsf{mach}}), \quad \mathsf{and} \quad rac{\| ilde{R}\|}{\|A\|} = \mathcal{O}(1),$$

we have

$$rac{\| ilde{Q}(\delta R)\|}{\|A\|} = \mathcal{O}(arepsilon_{ ext{mach}}).$$

Peter Blomgren (blomgren@sdsu.edu)

12. Stability of Householder QR for $A\vec{x} = \vec{b}$

Theorem — Householder-Triangularization + Back-Substitution Three Major Holes to Patch...

Solving $A\vec{x} = \vec{b}$, Using Householder *QR*-Factorization

8 of 8

We collect our findings, and note that as required

$$rac{\|\Delta A\|}{\|A\|} \leq rac{\|\delta A\|}{\|A\|} + rac{\|(\delta Q) ilde{R}\|}{\|A\|} + rac{\| ilde{Q}(\delta R)\|}{\|A\|} + rac{\|(\delta Q)(\delta R)\|}{\|A\|} = \mathcal{O}(arepsilon_{\mathsf{mach}}).$$

This completes the proof. \Box

If we combine this result with the accuracy theorem we showed last time, we get the following result about the accuracy of solutions of $A\vec{x} = \vec{b}$ using the Householder-Triangularization + Back-substitution algorithm:

Reference Stability of Algorithms Solving $A\vec{x} = \vec{b}$

 $\label{thm:continuity} Theorem — Householder-Triangularization + Back-Substitution \\ \textbf{Three Major Holes to Patch...}$

Patching Some Holes...

We have left three major holes in the argument — the statement, without* proof, that the individual steps are backward stable.

It is instructive to see at least one such proof from "scratch." — Next, we turn our attention to step-3, the back-substitution algorithm.

Even though back substitution is one of the easiest problems of numerical linear algebra, the stability proof is quite lengthy... and provides the general structure / workflow for all such proofs. \rightsquigarrow That will be our next order of business in [Lecture#13].

* For step-1 (the QR-factorization), we have "proof by reference."
