The Augmented Matrix [A b]

Given a matrix A and a column vector  $\vec{b}$ 

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \qquad \vec{b} = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix},$$

we define the augmented matrix

$$[A \ \vec{b}] = \left[ egin{array}{ccc|c} a_{11} & a_{12} & a_{13} & b_1 \ a_{21} & a_{22} & a_{23} & b_2 \ a_{31} & a_{32} & a_{33} & b_3 \end{array} 
ight]$$

We are going to operate on this augmented matrix using 3 fundamental operations...

Peter Blomgren (blomgren@sdsu.edu)

16. GE / LU-Factorization with Pivoting

**—** (5/31)

Gaussian Elimination GE: Instabilities, and Improvements

Introduction: GE — Something Familiar
GE, Backward Substitution, and LU-Factorization
Computational Complexity

Gaussian Elimination, Backward Substitution, and LU-Factorization

The goal is to apply a sequence of the operations on the augmented matrix

$$[A \ \vec{b}] = \left[ \begin{array}{ccc|c} a_{11} & a_{12} & a_{13} & b_1 \\ a_{21} & a_{22} & a_{23} & b_2 \\ a_{31} & a_{32} & a_{33} & b_3 \end{array} \right],$$

in order to transform it into the upper triangular form

$$\begin{bmatrix} \tilde{a}_{11} & \tilde{a}_{12} & \tilde{a}_{13} & \tilde{b}_1 \\ 0 & \tilde{a}_{22} & \tilde{a}_{23} & \tilde{b}_2 \\ 0 & 0 & \tilde{a}_{33} & \tilde{b}_3 \end{bmatrix}.$$

From this form we use **backward substitution** to get the solution:

$$x_3 \leftarrow \tilde{b}_3/\tilde{a}_{33}, \quad x_2 \leftarrow (\tilde{b}_2 - \tilde{a}_{23}x_3)/\tilde{a}_{22},$$
  
 $x_1 \leftarrow (\tilde{b}_1 - \tilde{a}_{12}x_2 - \tilde{a}_{13}x_3)/\tilde{a}_{11}.$

GE, Backward Substitution, and LU-Factorization Computational Complexity

Three Basic Operations on the Linear System / Augmented Matrix

We use three operations to simplify a linear system:

op#1 **Scaling** — Equation#i  $(E_i)$  can be multiplied by any non-zero constant  $\lambda$  with the resulting equation used in place of  $E_i$ . We denote this operation  $(\mathbf{E_i}) \leftarrow (\lambda \mathbf{E_i})$ .

op#2 **Scaled Addition** — Equation#j  $(E_j)$  can be multiplied by any non-zero constant  $\lambda$  and added to Equation#i  $(E_i)$  with the resulting equation used in place of  $E_i$ . We denote this operation  $(\mathbf{E_i}) \leftarrow (\mathbf{E_i} + \lambda \mathbf{E_i})$ .

op#3 **Reordering** — Equation#j  $(E_j)$  and Equation#i  $(E_i)$  can be transposed in order. We denote this operation  $(E_i) \leftrightarrow (E_i)$ .

 $\textbf{Peter Blomgren} \ \langle \texttt{blomgren@sdsu.edu} \rangle$

Gaussian Elimination GE: Instabilities, and Improvements

Introduction: GE — Something Familiar
GE, Backward Substitution, and LU-Factorization
Computational Complexity

GE+BS+LU

1 of 4

Given an augmented matrix

$$C = [A \ \vec{b}] = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \dots & a_{1m} & b_1 \\ a_{21} & a_{22} & a_{23} & \dots & a_{2m} & b_2 \\ a_{31} & a_{32} & a_{33} & \dots & a_{3m} & b_3 \\ \vdots & & \ddots & \vdots & \vdots \\ a_{m1} & a_{m2} & a_{m3} & \dots & a_{mm} & b_m \end{bmatrix}$$

We first make all the sub-diagonal entries in the first column zero:

for j=2:m [Eliminate the first column]  $\ell_{j1} \leftarrow -c_{j1}/c_{11} \\ r_{j} \leftarrow (\ell_{j1}r_{1}+r_{j}) \quad [r_{j} \text{ denotes elements in the } j \text{th row}]$  end

**—** (8/31)

Introduction: GE — Something Familiar GE, Backward Substitution, and LU-Factorization Computational Complexity

GE+BS+LU

∃ Movie

2 of 4

The pattern is clear... For a full implementation we eliminate all the sub-diagonal elements in columns  $1\rightarrow (m-1)$ :

for 
$$i=1:(m-1)$$
  
for  $j=(i+1):m$  [Eliminate the  $i$ th column]  
 $\ell_{ji} \leftarrow -c_{ji}/c_{ii}$   
 $r_j \leftarrow (\ell_{ji}r_i+r_j)$  [ $r_j$  -- elements in the  $j$ th row]  
end

Peter Blomgren (blomgren@sdsu.edu)

16. GE / LU-Factorization with Pivoting

**—** (9/31)

Gaussian Elimination GE: Instabilities, and Improvements

Introduction: GE — Something Familiar
GE, Backward Substitution, and LU-Factorization
Computational Complexity

GE+BS+LU

end

4 of 4

Now, if we are looking for the solution to  $A\vec{x} = \vec{b}$ , we simply apply backward substitution to the  $[U | \tilde{b}]$  system.

If we define  $L=M^{-1}$ ; — think of it as inverting (undoing) the triangularization of A

$$\mathtt{L} = \textit{M}_{1}^{-1} \textit{M}_{2}^{-1} \cdots \textit{M}_{m-1}^{-1} = \left[ \begin{array}{cccc} 1 \\ -\ell_{21} & 1 \\ -\ell_{31} & -\ell_{32} & 1 \\ \vdots & \vdots & \ddots & \ddots \\ -\ell_{m1} & -\ell_{m2} & \dots & -\ell_{m,m-1} & 1 \end{array} \right]$$

Then we have the **LU-Factorization** of A

$$A = LU$$
.

— (11/31)

Gaussian Elimination
GE: Instabilities, and Improvements

Introduction: GE — Something Familiar GE, Backward Substitution, and LU-Factorization Computational Complexity

GE+BS+LU

3 of 4

After the elimination step, we have the following scenario — the augmented matrix is now upper triangular; we identify the upper triangular part U, and the modified right-hand-side  $\tilde{b}$ , and collect the multipliers in matrices  $M_j$ 

We have the relation

$$\underbrace{M_{m-1}\cdot M_{m-2}\cdots M_{1}}_{C}\cdot C=M\cdot C=M\cdot [A\mid \vec{b}]=[U\mid \tilde{b}]=\tilde{C}$$

 $\textbf{Peter Blomgren} \ \langle \texttt{blomgren@sdsu.edu} \rangle$ 

16. GE / LU-Factorization with Pivoting

— (10/31)

Gaussian Elimination
GE: Instabilities, and Improvements

Introduction: GE — Something Familiar
GE, Backward Substitution, and LU-Factorization
Computational Complexity

Gaussian Elimination  $\leftrightarrow$  Matrix Multiplications

Supplemental

We can view the entire GE-algorithm as a sequence of matrix multiplications:

$$\underbrace{M_{m-1}M_{m-2}\cdots M_2M_1}_{M}A=U$$

and it follows that we can write

$$A = M^{-1}U = [M_1]^{-1}[M_2]^{-1} \dots [M_{m-2}]^{-1}[M_{m-1}]^{-1}U$$

The multiplication by the matrices  $[M_j]$  correspond to scaled row-addition; the inverse operation is scaled row-subtraction, hence

GE. Backward Substitution, and LU-Factorization Computational Complexity

Checking the Inverses of  $M_i$ 

Supplemental

When we perform the matrix-matrix multiplication, the sub-diagonal elements of  $[M_i]^{-1}$  (in column j, row  $k \ge j$ ) will multiply elements in row j (column k) of  $[M_i]$ (only the 1 on the diagonal). When that happens, the diagonal k-k element of  $[M_i]^{-1}$ will multiply the k-j-element of  $[M_i]$ , and we get

$$\mathsf{Product}(k,j) = -\ell_{k,j} \cdot 1 + 1 \cdot \ell_{k,j} = 0, \ k > j$$

All other off-diagonal elements are formed by (something) multiplying zero.

In summary, the only non-zeros elements in the product are the diagonal elements,

In the same way  $[M_i][M_i]^{-1} = I_n$ , hence the matrix we denoted  $[M_i]^{-1}$  really is the inverse of  $[M_i]$ .

Gaussian Elimination GE: Instabilities, and Improvements

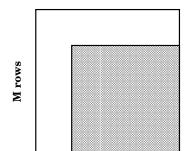

Introduction: GE — Something Familian GE, Backward Substitution, and LU-Factorization **Computational Complexity** 

GE+BS: Work Required

Elimination Step k

1 of 2

# **Gaussian Elimination:** Consider the kth elimination step: M columns

Peter Blomgren (blomgren@sdsu.edu)

k-1 untouched rows/cols

M-(k-1) changed rows/cols

In this step we need to touch (read from cache/memory, apply addition and/or multiplication) the shaded elements. The work required is directly proportional to the number shaded elements  $i^2$ , where i = (M - (k - 1)).

16. GE / LU-Factorization with Pivoting

**— (15/31)** 

Nailing Down the L in  $A = L \cdot U$ 

Supplemental

We now have expression for all the  $[M_i]^{-1}$ -matrices in the product  $M^{-1} = [M_1]^{-1}[M_2]^{-1} \dots [M_{m-2}]^{-1}[M_{m-1}]^{-1}$ . Consider  $[M_1]^{-1}[M_2]^{-1}$ :

$$\begin{bmatrix} \frac{1}{-\ell_{2,1}} & 1 & & \\ -\ell_{3,1} & 1 & & \\ \vdots & & \ddots & \\ -\ell_{m,1} & & & 1 \end{bmatrix} \begin{bmatrix} \frac{1}{-\ell_{3,2}} & 1 & & \\ -\ell_{3,2} & 1 & & \\ \vdots & & \ddots & \\ -\ell_{m,2} & & & 1 \end{bmatrix} = \begin{bmatrix} 1 & & & \\ -\ell_{2,1} & 1 & & \\ -\ell_{3,1} & -\ell_{3,2} & 1 & \\ \vdots & \vdots & \ddots & \\ -\ell_{m,1} & -\ell_{m,2} & & & 1 \end{bmatrix}$$

The argument can be extended to the entire product to show that

$$L = M^{-1} = \left[ \begin{array}{ccccc} 1 & & & & & & \\ -\ell_{2,1} & 1 & & & & & \\ -\ell_{3,1} & -\ell_{3,2} & 1 & & & & \\ \vdots & \vdots & \ddots & \ddots & \vdots & & \\ -\ell_{m,1} & -\ell_{m,2} & \cdots & -\ell_{m,m-1} & 1 \end{array} \right]$$
 Which is the matrix we build in our LU-factorization core.

Peter Blomgren (blomgren@sdsu.edu)

Gaussian Elimination
GE: Instabilities, and Improvements

Partial Pivoting
Scaled Partial Pivoting
Complete Pivoting

# **Pivoting Strategies**

Partial Pivoting

It is fairly easy to re-arrange the computation so that all multipliers are bounded by 1.

Partial pivoting adds  $\frac{m^2}{2}$  comparisons to the algorithm.

**Figure:** Illustration of elimination on the k th level. We search for the largest (in magnitude) pivot element in the k th column, among the diagonal+sub-diagonal elements (vertical blue band). Then we interchange the k th row with the row with the maximal pivot (illustrated with two horizontal red bands).

**— (19/31)** 

Gaussian Elimination GE: Instabilities, and Improvements

Partial Pivoting
Scaled Partial Pivoting
Complete Pivoting

Instability of Gaussian Elimination / LU-Factorization

As described, GE/LU can run into stability issues — consider the multipliers in the light of stability and floating-point errors

$$ilde{\ell}_{ji} = -c_{ij} \oslash c_{ii} = -rac{c_{ij}}{c_{ii}} (1+\epsilon), \,\, |\epsilon| \leq arepsilon_{\mathsf{mach}}$$

Hence, the absolute errors introduced in the multipliers are

$$\delta \ell_{ji} \sim arepsilon_{\sf mach} \left(rac{c_{ij}}{c_{ii}}
ight)$$

and if  $c_{ii}$  is close to zero, then the error may be very large (especially in comparison with other entries in the matrix).

#### We need to fix this...

Clearly, the smaller the multipliers, the smaller the errors...

Partial Pivoting Scaled Partial Pivoting Complete Pivoting

## Gaussian Elimination with Partial Pivoting

$$U = [A \ \vec{b}]$$

```
L = eye(m); P = eye(m); U = [A b];
2
   for k = 1:(m-1)
3
     Umax
                       = \max(abs(U(k:m,k)));
                       = find( abs(U(k:m,k)) == Umax );
     Umax_index
5
                       = Umax_index(1) + (k-1);
     U([j k],k:(m+1)) = U([k j],k:(m+1));
     L([j k],1:(k-1)) = L([k j],1:(k-1));
     P([j k],:)
                       = P([k j],:);
     for j = (k+1):m
                     = U(j,k) / U(k,k);
10
       U(j,k:(m+1)) = U(j,k:m+1) - L(j,k)*U(k,k:(m+1));
11
12
     end
13
   end
```

The algorithm yields

$$PA = LU$$
.

It is much more stable than our initial two implementations of Gaussian Elimination, but it is **not** fail-safe.

"Scale Invariant PP" ???

We can pre-compute the scales s(i) and make the pivoting decision based on the values of B(i,i)/s(i) and B(j,i)/s(j), j=(i+1):n.

```
s = zeros(m.1):
for i=1:m
  s(i) = max(abs(B(i,:)));
end
for i=1:(m-1)
 Bmax = max(abs(B(i:m,i)./s(i:m)));
 Bmax_index = find(abs(B(i:m,i)./s(i:m)) == Bmax);
 j = Bmax_index(1) + (i-1);
 B([j i],i:(m+1)) = B([i j],i:(m+1));
 L([j i],1:(i-1)) = L([i j],1:(i-1));
 P([i i],:) = P([i i],:);
 for j=(i+1):m
  L(j,i) = -B(j,i) / B(i,i);
  B(j,i:(m+1)) = L(j,i)*B(i,i:(m+1)) + B(j,i:(m+1));
 end
end
```

Gaussian Elimination GE: Instabilities, and Improvements

Partial Pivoting
Scaled Partial Pivoting
Complete Pivoting

Gaussian Elimination with Partial Pivoting: Breakdown

If we apply GE+PP to a system where the **scales** of the different equations are significantly different, the algorithm may break down (unnecessarily lose precision) e.g

$$\begin{bmatrix} 1 & -2 & 3 \\ 1,000,000 & 2,000,000 & 3,000,000 \\ 0.000001 & -0.000002 & -0.000003 \end{bmatrix} \vec{x} = \begin{bmatrix} 4 \\ 5,000,000 \\ 0.000001 \end{bmatrix}$$

In order to improve stability of GE+PP we must take scale into consideration.

One definition of scale: s(i) = max(abs(B(i,:))), *i.e.* the scale of row #i equals to the magnitude of the largest element on that row.

Peter Blomgren (blomgren@sdsu.edu)

16. GE / LU-Factorization with Pivoting

**— (22/31)** 

Gaussian Elimination GE: Instabilities, and Improvements

Partial Pivoting
Scaled Partial Pivoting

### GE+SPP: Work Comparison

```
s = zeros(m,1);
for i=1:m
    s(i) = max(abs(B(i,:)));
end
for i=1:(m-1)
    Bmax = max(abs(B(i:m,i)./s(i:m)));
    Bmax.index = find( abs(B(i:m,i)./s(i:m)) == Bmax );
    j = Bmax.index(1) + (i-1);
    B([j i],i:(m+1)) = B([i j],i:(m+1));
    L([j i],1:(i-1)) = L([i j],1:(i-1));
    P([j i],:) = P([i j],:);
    for j=(i+1):m
        L(j,i) = -B(j,i) / B(i,i);
        B(j,i:(m+1)) = L(j,i)*B(i,i:(m+1)) + B(j,i:(m+1));
end
end
```

Note that the scale computation touches every element in the matrix, hence it adds

 $\mathcal{O}\left(\mathsf{m}^2\right)$  additional operations.

Since this algorithm overall requires  $\mathcal{O}\left(m^3\right)$  operations, the overhead of scaled partial pivoting does not add a significant amount of work.

-(24/31)

Gaussian Elimination GE: Instabilities, and Improvements

Partial Pivoting
Scaled Partial Pivoting
Complete Pivoting

# GE+SPP: Wait a Minute! — The Scale Changes

Since we are modifying the rows in each elimination step, it seems likely that the scale of the row change. Should we recompute them???

```
s = zeros(m,1);
for i=1:(m-1)
  for k=i:m
    s(k) = max(abs(B(k,:)));
  end
Bmax = max(abs(B(i:m,i)./s(i:m)));
Bmax_index = find( abs(B(i:m,i)./s(i:m)) == Bmax );
  j = Bmax_index(1) + (i-1);
  B([j i],i:(m+1)) = B([i j],i:(m+1));
  L([j i],1:(i-1)) = L([i j],1:(i-1));
  P([j i],:) = P([i j],:);
  for j=(i+1):m
    L(j,i) = -B(j,i) / B(i,i);
    B(j,i:(m+1)) = L(j,i)*B(i,i:(m+1)) + B(j,i:(m+1));
end
```

Let's call this GE+Rescaled-SPP (GE+RSPP). Since we are touching all the remaining elements in the matrix in each iteration, this configuration adds

 $\mathcal{O}\left(m^3\right)$  additional operations,

which is a significant amount of work.

Scaled Partial Pivoting Complete Pivoting

## Illustration: Gaussian Elimination with Complete Pivoting

Gaussian Elimination

[**Left**] Illustration of elimination on the *k*th level. We search for the largest (in magnitude) pivot element in the sub-matrix indicated with blue; the pivot is marked with a black dot.

[Center] We interchange the corresponding rows, to move the pivot to the "active" row.

[**Right**] We interchange the columns to move the pivot to the "active"  $A_{kk}$  pivot location.

**— (27/31)** 

GE with Complete Pivoting

GE+CP

If/when a problem warrants this (GE+RSPP) approach due to high accuracy demands, and we are willing to trade significant time/work for it) **complete pivoting** should be used instead.

```
for i=1:(m-1)
  Bmax = max(max(abs(B(i:m,i:m))));
  [Bmax_r,Bmax_c] = find( abs(B(i:m,i:m)) == Bmax );
  j_r = Bmax_r(1) + (i-1);
  j_c = Bmax_c(1) + (i-1);
  B([j_r i],i:(m+1)) = B([i j_r],i:(m+1));
  L([j_r i],1:(i-1)) = L([i j_r],1:(i-1));
  P([j_r i],:) = P([i j_r],:);
  B(:,[j_c i]) = B(:,[i j_c]);
  for j=(i+1):m
  L(j,i) = -B(j,i) / B(i,i);
  B(j,i:(m+1)) = L(j,i)*B(i,i:(m+1)) + B(j,i:(m+1));
  end
end
```

**WARNING!!!** — When the columns are interchanged, the unknowns are re-ordered. We have to implement extra book-keeping in order to keep track!

GE with Complete Pivoting

Book-keeping

GE+CP

```
col_idx = (1:m)';
for i=1:(m-1)
  Bmax = max(max(abs(B(i:m,i:m))));
  [Bmax_r, Bmax_c] = find(abs(B(i:m,i:m)) == Bmax);
  i_r = Bmax_r(1) + (i-1):
   _{c} = Bmax_{c}(1) + (i-1):
  B([j_r i],i:(m+1)) = B([i j_r],i:(m+1));
  L([j_r i],1:(i-1)) = L([i j_r],1:(i-1));
                    = P([i j_r],:);
 P([j_r i],:)
                     = B(:,[i j_c]);
 B(:,[j_c i])
 col_idx([j_c i]) = col_idx([i j_c]);
 for j=(i+1):m
  L(j,i) = -B(j,i) / B(i,i);
  B(j,i:(m+1)) = L(j,i)*B(i,i:(m+1)) + B(j,i:(m+1));
 end
end
```

After completion,  $col_idx(i)$  contains the original index of the variable currently called x(i).

After GE+CP, we solve for  $\vec{x}$  using standard Backward Substitution, then we use the col\_idx array to put the solution array back in the correct order:
