The BFGS Method

イロト イポト イヨト イヨト

Quasi-Newton methods require **only the gradient** (like steepest descent) of the objective to be computed at each iterate.

By successive measurements of the gradient, Quasi-Newton methods build a quadratic model of the objective function which is sufficiently good that **superlinear** convergence is achieved.

Quasi-Newton methods are much faster than steepest descent (and coordinate descent) methods.

Since second derivatives (the Hessian) are not required, quasi-Newton methods are **sometimes** more efficient (as measured by total work / "wall-clock computational time") than Newton methods, especially when Hessian evaluation is slow/expensive.

イロト イポト イヨト イヨト

The BFGS Method: Introduction

The BFGS method is named for its discoverers: BROYDEN-FLETCHER-GOLDFARB-SHANNO, and is the most popular quasi-Newton method.

We first derive the DFP method (a close relative; named after DAVIDON-FLETCHER-POWELL) and then the BFGS method; and look at some properties and practical implementation details.

The derivation starts with the quadratic model

$$m_k(\mathbf{\bar{p}}) = f(\mathbf{\bar{x}}_k) + \nabla f(\mathbf{\bar{x}}_k)^T \mathbf{\bar{p}} + \frac{1}{2} \mathbf{\bar{p}}^T B_k \mathbf{\bar{p}}$$

at the current iterate $\bar{\mathbf{x}}_k$. B_k is a symmetric positive definite matrix (model Hessian) that will be **updated** in every iteration.

(D) (A) (A) (A) (A)

Quasi-Newton Methods BFGS Variants	Introduction The BFGS Method	
The BEGS Method: Introduction	Standard Stuff	2 of 3

Given this convex quadratic model, we can write down the minimizer $\mathbf{\bar{p}}_k$ explicitly as

$$\mathbf{\bar{p}}_k = -B_k^{-1} \nabla f(\mathbf{\bar{x}}_k).$$

We can compute the search direction $\mathbf{\bar{p}}_k$ using *e.g.* the Cholesky factorization, or a (P)CG-iteration; once we have $\mathbf{\bar{p}}_k$ we find the new iterate:

$$\mathbf{\bar{x}}_{k+1} = \mathbf{\bar{x}}_k + \alpha_k \mathbf{\bar{p}}_k,$$

where we require that the step length α_k satisfies *e.g.* the Wolfe conditions:

$$\begin{array}{rcl} f(\bar{\mathbf{x}}_k + \alpha \bar{\mathbf{p}}_k) &\leq & f(\bar{\mathbf{x}}_k) + c_1 \alpha \bar{\mathbf{p}}_k^T \nabla f(\bar{\mathbf{x}}), & c_1 \in (0,1) \\ \bar{\mathbf{p}}_k^T \nabla f(\bar{\mathbf{x}}_k + \alpha \bar{\mathbf{p}}_k) &\geq & c_2 \bar{\mathbf{p}}_k^T \nabla f(\bar{\mathbf{x}}_k), & c_2 \in (c_1,1). \end{array}$$

Introduction The BFGS Method

The BFGS Method: Introduction

So far we have not really done anything new — the key difference compared with the linesearch Newton method is that we are using an approximate Hessian $B_k \neq \nabla^2 f(\mathbf{\bar{x}}_k)$.

Instead to computing a completely new B_k in each iteration, we will update

 $B_{k+1} = B_k +$ "something,"

using partial about the curvature at step #k. Thus we get a new model

$$m_{k+1}(\mathbf{\bar{p}}) = f(\mathbf{\bar{x}}_{k+1}) + \nabla f(\mathbf{\bar{x}}_{k+1})^T \mathbf{\bar{p}} + \frac{1}{2} \mathbf{\bar{p}}^T B_{k+1} \mathbf{\bar{p}}.$$

Clearly, for this to make sense we must impose some conditions on the update.

The BFGS Method: Conditions on B_{k+1}

We impose two conditions on the new model $m_{k+1}(\mathbf{\bar{p}})$:

[1,2]
$$m_{k+1}(\mathbf{\bar{p}})$$
 must match the gradient of the objective function in $\mathbf{\bar{x}}_k$ and $\mathbf{\bar{x}}_{k+1}$.

The second condition is satisfied by construction, since

$$abla m_{k+1}(\mathbf{\bar{0}}) =
abla f(\mathbf{\bar{x}}_{k+1}).$$

The first condition gives us

$$\nabla m_{k+1}(-\alpha_k \mathbf{\bar{p}}_k) = \nabla f(\mathbf{\bar{x}}_{k+1}) - \alpha_k B_{k+1} \mathbf{\bar{p}}_k = \nabla f(\mathbf{\bar{x}}_k).$$

With a little bit of re-arrangement we get

$$\alpha_{\mathbf{k}} \mathbf{B}_{\mathbf{k}+1} \mathbf{\bar{p}}_{\mathbf{k}} = \nabla \mathbf{f}(\mathbf{\bar{x}}_{\mathbf{k}+1}) - \nabla \mathbf{f}(\mathbf{\bar{x}}_{\mathbf{k}}).$$

Quasi-Newton Methods	Introduction
BFGS Variants	The BFGS Method

The BFGS Method: Conditions on B_{k+1}

We clean up the notation by introducing $(\bar{\mathbf{x}}_k, \text{ and } \bar{\mathbf{y}}_k)$:

We can now express the condition on B_{k+1} in terms of $\mathbf{\bar{s}}_k$ and $\mathbf{\bar{y}}_k$:

Secant Equation $B_{k+1} \overline{s}_k = \overline{y}_k.$

By pre-multiplying the secant equation by $\mathbf{\bar{s}}_{k}^{T}$ we get the

If we impose the Wolfe, or strong Wolfe condition on the line search procedure, the curvature condition will always hold, since

$$\nabla f(\mathbf{\bar{x}}_{k+1})^T \mathbf{\bar{s}}_k \geq c_2 \nabla f(\mathbf{\bar{x}}_k)^T \mathbf{\bar{s}}_k,$$

by the (curvature) Wolfe condition, and therefore

$$\mathbf{\bar{y}}_{k}^{T}\mathbf{\bar{s}}_{k} \geq (c_{2}-1)\alpha_{k}\nabla f(\mathbf{\bar{x}}_{k})^{T}\mathbf{\bar{p}}_{k},$$

where the right-hand-side is positive since $c_2 < 1$ and $\mathbf{\bar{p}}_k$ is a descent direction.

When the curvature condition is satisfied, the secant equation always has at least one solution B_{k+1} .

(D) (A) (A) (A) (A)

The BFGS Method: More Conditions on B_{k+1}

It turns out that there are infinitely many symmetric positive definite matrices B_{k+1} which satisfy the secant equation.

Degrees of Freedom	Conditions Imposed
n(n+1)/2 — Symmetric	n — The Secant Equation
	<i>n</i> — Principal minors positive (PD)

To determine B_{k+1} uniquely we must impose additional conditions — we will select the B_{k+1} that is closest to B_k in some sense:

Matrix-Minimization-Problem

$$B_{k+1} = \arg\min_{B} ||B - B_k||_{\text{some-norm}}$$

subject to $B = B^T$, $B\bar{\mathbf{s}}_k = \bar{\mathbf{y}}_k$.

-(10/26)

・ロト ・ 同ト ・ ヨト ・ ヨト

Quasi-Newton Methods BFGS Variants The BFGS Method

The BFGS Method: More Conditions on B_{k+1}

Each choice of matrix norm in this matrix-minimization-problem (MMP) gives rise to a different quasi-Newton method.

The weighted Frobenius norm

$$||A||_{W} = ||W^{1/2}AW^{1/2}||_{F} = ||C||_{F} = \sqrt{\sum_{i=0}^{n} \sum_{j=0}^{n} c_{ij}^{2}}$$

allows easy solution of the MMP, and gives rise to a scale-invariant optimization method.

The matrix W is chosen to be the inverse G_k^{-1} of the **average Hessian**

$$G_k = \int_0^1 \nabla^2 f(\mathbf{ar{x}}_k + \tau lpha_k \mathbf{ar{p}}_k) \, d au.$$

イロト イポト イヨト イヨト

[SUPPLEMENTAL]

Square Roots of SPD Matrices

- A positive semi-definite matrix, M has a unique positive semi-definite square root, $R = M^{1/2}$.
- When $M = X\Lambda X^{-1} \stackrel{\text{SPD}}{=} Q\Lambda Q^T$, let $R = QSQ^T$, and

$$R^{2} = (QSQ^{T})^{2} = QSQ^{T}QSQ^{T} = QSSQ^{T} = QS^{2}Q^{T} = M,$$

showing that

$$S = \Lambda^{1/2}$$
, and therefore $R = Q \Lambda^{1/2} Q^T$

• \exists other approaches.

With this weighting matrix and norm, the unique solution of the MMP is

$$B_{k+1} = \left(I - \gamma_k \bar{\mathbf{y}}_k \bar{\mathbf{s}}_k^T\right) B_k \left(I - \gamma_k \bar{\mathbf{s}}_k \bar{\mathbf{y}}_k^T\right) + \gamma_k \bar{\mathbf{y}}_k \bar{\mathbf{y}}_k^T, \quad \gamma_k = \frac{1}{\bar{\mathbf{y}}_k^T \bar{\mathbf{s}}_k}.$$

Note that γ_k is a scalar, and $\mathbf{\bar{y}}_k \mathbf{\bar{s}}_k^T$, $\mathbf{\bar{s}}_k \mathbf{\bar{y}}_k^T$, and $\mathbf{\bar{y}}_k \mathbf{\bar{y}}_k^T$ are rank-one matrices.

This is the original Davidon-Fletcher-Powell (DFP) method suggested by W.C. Davidon in 1959.

The original paper describing this revolutionary idea — the first quasi-Newton method — was not accepted for publication. It later appeared in **1991** in the first issue the the SIAM Journal on Optimization.

Fletcher and Powell demonstrated that this algorithm was much faster and more reliable than existing methods (at the time). This revolutionized the field of non-linear optimization.

Quasi-Newton Methods BFGS Variants

Introduction The BFGS Method

The DFP Method: Cleaning Up

The inverse of B_k is useful for the implementation of the method, since it allows the search direction $\mathbf{\bar{p}}_k$ to be computed using a simple matrix-vector product. We let

$$H_k = B_k^{-1}$$

and use

Sherman-Morrison-Woodbury formula

If $A \in \mathbb{R}^{n \times n}$ is non-singular and $\mathbf{\bar{a}}, \mathbf{\bar{b}} \in \mathbb{R}^{n}$, and if

$$B = A + \mathbf{\bar{a}}\mathbf{\bar{b}}^T$$

then

$$B^{-1} = A^{-1} - \frac{A^{-1} \overline{\mathbf{a}} \overline{\mathbf{b}}^T A^{-1}}{1 + \overline{\mathbf{b}}^T A^{-1} \overline{\mathbf{a}}}.$$

Peter Blomgren, (blomgren.peter@gmail.com)

Quasi-Newton Methods — The BFGS Method — (14/26)

1 of 2

With a little bit of linear algebra we end up with

$$\mathcal{H}_{k+1} = \mathcal{H}_k - \underbrace{\frac{\mathcal{H}_k \bar{\mathbf{y}}_k \bar{\mathbf{y}}_k^T \mathcal{H}_k}{\bar{\mathbf{y}}^T \mathcal{H}_k \bar{\mathbf{y}}_k}}_{\mathbf{Update \#1}} + \underbrace{\frac{\bar{\mathbf{s}}_k \bar{\mathbf{s}}_k^T}{\bar{\mathbf{y}}_k^T \bar{\mathbf{s}}_k}}_{\mathbf{Update \#2}} \ .$$

Both the update terms are rank-one matrices; so that H_k undergoes a rank-2 modification in each iteration.

This is the **fundamental idea of quasi-Newton updating:** instead of recomputing the matrix (-inverse) from scratch each time around, we apply a simple modification which combines the more recently observed information about the objective with existing knowledge embedded in the current Hessian approximation.

Improving on DFP — The BFGS Method

The DFP method is quite effective, but once the quasi-Newton idea was accepted by the optimization community is was quickly superseded by the BFGS method.

BFGS updating is derived by instead of imposing conditions on the Hessian approximations B_k , we impose conditions directly on the inverses H_k .

The updated approximation must be symmetric positive definite, and must satisfy the **secant equation** in the form

 $\mathbf{H}_{\mathbf{k}+1}\mathbf{\bar{y}}_{\mathbf{k}} = \mathbf{\bar{s}}_{\mathbf{k}},$ compare: $B_{k+1}\mathbf{\bar{s}}_k = \mathbf{\bar{y}}_k.$

We get a slightly different matrix minimization problem...

イロン イヨン イヨン イヨン

Introduction The BFGS Method

The BFGS Matrix Minimization Problem

Matrix-Minimization-Problem (BFGS)

$$H_{k+1} = \arg\min_{H} ||H - H_k||_{\text{some-norm}}$$

subject to $H = H^T$, $H\bar{\mathbf{y}}_k = \bar{\mathbf{s}}_k$

If we again choose the weighted Frobenius norm (with the same weight), then we get the unique update

$$H_{k+1} = \left(I - \rho_k \bar{\mathbf{s}}_k \bar{\mathbf{y}}_k^T\right) H_k \left(I - \rho_k \bar{\mathbf{y}}_k \bar{\mathbf{s}}_k^T\right) + \rho_k \bar{\mathbf{s}}_k \bar{\mathbf{s}}_k^T, \quad \rho_k = \frac{1}{\bar{\mathbf{y}}_k^T \bar{\mathbf{s}}_k},$$

which translated back to the Hessian approximation yields

$$B_{k+1} = B_k - \frac{B_k \bar{s}_k \bar{s}_k^T B_k}{\bar{s}_k^T B_k \bar{s}_k} + \frac{\bar{y}_k \bar{y}_k^T}{\bar{y}_k^T \bar{s}_k}.$$

BFGS vs. DFP Updates

BFGS Update —

$$\begin{aligned} H_{k+1} &= \left(I - \rho_k \bar{\mathbf{s}}_k \bar{\mathbf{y}}_k^T \right) H_k \left(I - \rho_k \bar{\mathbf{y}}_k \bar{\mathbf{s}}_k^T \right) + \rho_k \bar{\mathbf{s}}_k \bar{\mathbf{s}}_k^T, \quad \rho_k = \frac{1}{\bar{\mathbf{y}}_k^T \bar{\mathbf{s}}_k}, \\ B_{k+1} &= B_k - \frac{B_k \bar{\mathbf{s}}_k \bar{\mathbf{s}}_k^T B_k}{\bar{\mathbf{s}}_k^T B_k \bar{\mathbf{s}}_k} + \frac{\bar{\mathbf{y}}_k \bar{\mathbf{y}}_k^T}{\bar{\mathbf{y}}_k^T \bar{\mathbf{s}}_k}. \end{aligned}$$

DFP Update —

$$B_{k+1} = (I - \gamma_k \bar{\mathbf{y}}_k \bar{\mathbf{s}}_k^T) B_k (I - \gamma_k \bar{\mathbf{s}}_k \bar{\mathbf{y}}_k^T) + \gamma_k \bar{\mathbf{y}}_k \bar{\mathbf{y}}_k^T, \quad \gamma_k = \frac{1}{\bar{\mathbf{y}}_k^T \bar{\mathbf{s}}_k}.$$
$$H_{k+1} = H_k - \frac{H_k \bar{\mathbf{y}}_k \bar{\mathbf{y}}_k^T H_k}{\bar{\mathbf{y}}^T H_k \bar{\mathbf{y}}_k} + \frac{\bar{\mathbf{s}}_k \bar{\mathbf{s}}_k^T}{\bar{\mathbf{y}}_k^T \bar{\mathbf{s}}_k}.$$

The BFGS Method: Summary

The cost per iteration is

- $\mathcal{O}(n^2)$ arithmetic operations
- function evaluation
- gradient evaluation

The convergence rate is

• Super-linear

Newton's method converges quadratically, but the cost per iteration is higher — it requires the solution of a linear system. In addition Newton's method requires the calculation of second derivatives whereas the BFGS method does not.

Quasi-Newton Methods	Introduction
BFGS Variants	The BFGS Method

The BFGS Method: Stability and Self-Correction

If at some point $\rho_k = 1/\bar{\mathbf{y}}_k^T \bar{\mathbf{s}}_k$ becomes large, *i.e.* $\bar{\mathbf{y}}_k^T \bar{\mathbf{s}}_k \sim 0$, then from the update formula

$$H_{k+1} = \left(I - \rho_k \mathbf{\bar{s}}_k \mathbf{\bar{y}}_k^T\right) H_k \left(I - \rho_k \mathbf{\bar{y}}_k \mathbf{\bar{s}}_k^T\right) + \rho_k \mathbf{\bar{s}}_k \mathbf{\bar{s}}_k^T$$

we see that H_{k+1} becomes large.

If for this, or some other, reason H_k becomes a poor approximation of $\left[\nabla^2 f(\bar{\mathbf{x}}_k)\right]^{-1}$ for some k, is there any hope of correcting it?

It has been shown that the BFGS method has **self-correcting properties**. — If H_k incorrectly estimates the curvature of the objective function, and if this estimate slows down the iteration, then the Hessian approximation will tend to correct itself within a few steps.

The BFGS Method: Stability and Self-Correction

The self-correcting properties stand and fall with the quality of the line search! — The Wolfe conditions ensure that the model captures appropriate curvature information.

The DFP method is less effective at self-correcting bad Hessian approximations.

Practical Implementation Details:

- The linesearch should always test $\alpha = 1$ first, because this step length will eventually be accepted, thus creating super-linear convergence.
- The linesearch can be somewhat "sloppy:" $c_1 = 10^{-4}$ and $c_2 = 0.9$ are commonly used values in the Wolfe conditions.
- The initial matrix H₀ should not be too large, if H₀ = βI, then the first step is **p**₀ = −β∇f(**x**₀) which may be too long if β is large, often H₀ is rescaled before the update H₁ is computed:

$$H_0 \leftarrow \frac{\bar{\mathbf{y}}_k^T \bar{\mathbf{s}}_k}{\bar{\mathbf{y}}_k^T \bar{\mathbf{y}}_k} I.$$

イロン イヨン イヨン イヨン

Forming the $n \times n$ dense matrix H_k can be quite expensive for large problems. L-BFGS stores a limited history of the BFGS update vectors $\mathbf{\bar{s}}_k$ and $\mathbf{\bar{y}}_k$ (which are size n), and use these to "implicitly" form the matrix operations.

In standard BFGS, the current H_k contains updates all the way back to initial step $\{\bar{\mathbf{s}}_j, \bar{\mathbf{y}}_j\}_{j=0}^{k-1}$, whereas L-BFGS only uses a limited number of "recent" updates; so that the action of \tilde{H}_k is formed by application of $\{\bar{\mathbf{s}}_j, \bar{\mathbf{y}}_j\}_{j=\max(0,k-m)}^{k-1}$.

イロト イポト イヨト イヨト

Given a local initial positive definite model for the Hessian, \tilde{H}_k :

(a)
$$\mathbf{\bar{v}} = \nabla f(\mathbf{\bar{x}}_k)$$

(a) $\alpha_j = \rho_j \mathbf{\bar{s}}_j^T \mathbf{\bar{v}}, \quad \mathbf{\bar{v}} = \mathbf{\bar{v}} - \alpha_j \mathbf{\bar{y}}_j, \quad j = k - 1, \dots, k - m.$
(a) $\mathbf{\bar{w}} = \tilde{H}_k \mathbf{\bar{v}}$
(a) $\beta_j = \rho_j \mathbf{\bar{y}}_j^T \mathbf{\bar{w}}, \quad \mathbf{\bar{w}} = \mathbf{\bar{w}} + \mathbf{\bar{s}}_j (\alpha_j - \beta_j), \quad j = k - m, \dots, k - 1$
(b) Now, use $\mathbf{\bar{p}}_k = -\mathbf{\bar{w}} \quad (\approx -H_k \nabla f(\mathbf{\bar{x}}_k)).$
